Simple 3-state microsimulation model
Includes age and sex specific probability of dying when healthy

The DARTH workgroup

Developed by the Decision Analysis in R for Technologies in Health (DARTH) workgroup:

Fernando Alarid-Escudero, PhD (1)

Eva A. Enns, MS, PhD (2)

M.G. Myriam Hunink, MD, PhD (3,4)

Hawre J. Jalal, MD, PhD (5)

Eline M. Krijkamp, MSc (3)

Petros Pechlivanoglou, PhD (6,7)

Alan Yang, MSc (7)

In collaboration of:

1. Drug Policy Program, Center for Research and Teaching in Economics (CIDE) - CONACyT, Aguas-calientes, Mexico
2. University of Minnesota School of Public Health, Minneapolis, MN, USA
3. Erasmus MC, Rotterdam, The Netherlands
4. Harvard T.H. Chan School of Public Health, Boston, USA
5. University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, USA
6. University of Toronto, Toronto ON, Canada
7. The Hospital for Sick Children, Toronto ON, Canada

Change `eval` to `TRUE` if you want to knit this document.

```r
rm(list = ls())       # clear memory (removes all the variables from the workspace)
```

01 Load packages

```r
if (!require('pacman')) install.packages('pacman'); library(pacman) # use this package to conveniently
# load (install if required) packages from CRAN
p_load("here", "dplyr", "devtools", "scales", "ellipse", "ggplot2", "lazyeval", "igraph", "ggraph", "re
# load (install if required) packages from GitHub
# install_github("DARTH-git/dampack", force = TRUE) # Uncomment if there is a newer version
# install_github("DARTH-git/darthtools", force = TRUE) # Uncomment if there is a newer version
p_load_gh("DARTH-git/dampack", "DARTH-git/darthtools")
```

02 Load functions

```r
# No functions needed
```

03 Input model parameters

```r
set.seed(1)  # set the seed

# Model structure
v_n   <- c("healthy", "sick", "dead")      # vector with state names
n_t   <- 60                                # number of cycles
n_i   <- 10000                             # number of individuals
d_e <- d_c <- 0.03                         # equal discount of costs and QALYs by 3%

#### Deterministic analysis ####

# Transition probabilities
p_HS        <- 0.05     # probability healthy -> sick
p_HD_female <- 0.0382   # probability health -> dead when female
p_HD_male   <- 0.0463   # probability health -> dead when male
p_SD        <- 0.1      # probability sick -> dead

# Costs inputs
c_H  <- 1500      # cost of one cycle in healthy state
c_S  <- 5000      # cost of one cycle in sick state
c_D  <- 0

# utility inputs
```

```r
u_H  <- 1          # utility when healthy
u_S  <- 0.85       # utility when sick
u_D  <- 0          # utility when dead

n_states   <- length(v_n)                    # number of states

# calculate discount weights for costs for each cycle based on discount rate d_c
v_dwc <- 1 / (1 + d_e) ^ (0:n_t)
# calculate discount weights for effectiveness for each cycle based on discount rate d_e
v_dwe <- 1 / (1 + d_c) ^ (0:n_t)

m_p_HD      <- data.frame(Sex = c("Female", "Male"), p_HD = c(p_HD_female, p_HD_male))
```

04 Sample individual level characteristics

04.1 Static characteristics

```r
# randomly sample the sex of an individual (50% female)
v_sex <- sample(x = c("Female", "Male"), prob = c(0.5, 0.5), size = n_i, replace = TRUE)
df_X  <- data.frame(ID = 1:n_i, Sex = v_sex)
```

04.2 Dynamic characteristics

```r
# Specify the initial health state of the individuals
# everyone begins in the healthy state (in this example)
v_M_init  <- rep("healthy", times = n_i)
```

05 Define Simulation Functions

05.1 Probability function

The function that updates the transition probabilities of every cycle is shown below.

```r
Probs <- function(M_t, df_X) {
  # Arguments:
    # M_t:  health state occupied at cycle t (character variable)
    # df_X: data frame with individual characteristics data
  # Returns:
    # transition probabilities for that cycle

  # create matrix of state transition probabilities
  m_p_t           <- matrix(0, nrow = n_states, ncol = n_i)
  rownames(m_p_t) <-  v_n  # give the state names to the rows
```

```
  # lookup baseline probability and rate of dying based on individual characteristics
  p_HD_all <- inner_join(df_X, m_p_HD, by = c("Sex"))
  p_HD     <- p_HD_all[M_t == "healthy", "p_HD"]

  # update m_p_t with the appropriate probabilities
  # transition probabilities when healthy
  m_p_t[, M_t == "healthy"] <- rbind(1 - p_HD - p_HS, p_HS, p_HD)
  # transition probabilities when sick
  m_p_t[, M_t == "sick"]    <- rbind(0, 1 - p_SD, p_SD)
  # transition probabilities when dead
  m_p_t[, M_t == "dead"]    <- rbind(0, 0, 1)
  return(t(m_p_t))
}
```

05.2 Cost function

The `Costs` function estimates the costs at every cycle.

```
Costs <- function (M_t) {
  # M_t: current health state
  c_t <- c()
  c_t[M_t == "dead"]    <- c_D    # costs at dead state
  c_t[M_t == "healthy"] <- c_H    # costs accrued by being healthy this cycle
  c_t[M_t == "sick"]    <- c_S    # costs accrued by being sick this cycle

  return(c_t)  # return costs accrued this cycle
}
```

05.3 Health outcome function

The `Effs` function to update the utilities at every cycle.

```
Effs <- function (M_t) {
  # M_t: current health state
  q_t <- c()
  q_t[M_t == "dead"]    <- u_D    # QALYs at dead state
  q_t[M_t == "healthy"] <- u_H    # QALYs accrued by being healthy this cycle
  q_t[M_t == "sick"]    <- u_S    # QALYs accrued by being sick this cycle

  return(q_t)  # return the QALYs accrued this cycle
}
```

06 Run Microsimulation

```
MicroSim <- function(n_i, df_X, seed = 1) {
# Arguments:
  # n_i:     number of individuals
  # df_X:    data frame with individual data
```

```r
    # seed:      defauls is 1
  # Returns
    # a list with information about the individuals transitions, associated costs and
    # effects and total costs and rewards

    set.seed(seed) # set the seed

    # create three matrices called m_M, m_C and m_E
    # number of rows is equal to the n_i, the number of columns is equal to n_t
    # (the initial state and all the n_t cycles)
    # m_M is used to store the health state information over time for every individual
    # m_C is used to store the costs information over time for every individual
    # m_E is used to store the effects information over time for every individual

    m_M <- m_C <- m_E <-  matrix(nrow = n_i, ncol = n_t + 1,
                                      dimnames = list(paste("ind"  , 1:n_i, sep = " "),
                                                      paste("cycle", 0:n_t, sep = " ")))

    m_M[, 1] <- v_M_init          # initial health state
    m_C[, 1] <- Costs(m_M[, 1])   # costs accrued during cycle 0
    m_E[, 1] <- Effs(m_M[, 1])    # QALYs accrued during cycle 0

    # open a loop for time running cycles 1 to n_t
    for (t in 1:n_t) {
      # calculate the transition probabilities for the cycle based on health state t
      m_P <- Probs(m_M[, t], df_X)
      # sample the current health state and store that state in matrix m_M
      m_M[, t + 1]  <- samplev(m_P)
      m_C[, t + 1]  <- Costs(m_M[, t + 1])   # calculate costs
      m_E[, t + 1]  <- Effs (m_M[, t + 1])   # calculate QALYs

      # Display simulation progress
      if(t/(n_t/10) == round(t/(n_t/10), 0)) { # display progress every 10%
        cat('\r', paste(t/n_t * 100, "% done", sep = " "))
      }

    } # close the loop for the time points

    # calculate
    tc <- m_C %*% v_dwc    # total (discounted) cost per individual
    te <- m_E %*% v_dwe    # total (discounted) QALYs per individual
    tc_hat <- mean(tc)     # average (discounted) cost
    te_hat <- mean(te)     # average (discounted) QALYs

    # store the results from the simulation in a list
    results <- list(m_M = m_M, m_C = m_C, m_E = m_E, tc = tc , te = te, tc_hat = tc_hat,
                  te_hat = te_hat)

    return(results)  # return the results

} # end of the MicroSim function

# By specifying all the arguments in the `MicroSim()` the simulation can be started
```

```
# Run the simulation model
outcomes <- MicroSim(n_i = n_i, df_X = df_X, seed = 1)

# Show results
results  <- data.frame("Total Cost" = outcomes$tc_hat, "Total QALYs" = outcomes$te_hat)
results
```

07 Visualize results

```
options(scipen = 999)
plot(density(outcomes$tc), main = paste("Total cost per person"), xlab = "Cost ($)")
plot(density(outcomes$te), main = paste("Total QALYs per person"), xlab = "QALYs")
plot_m_TR(outcomes$m_M)    # health state trace
```
